A study was performed to clarify the function of IL-23 in the development of autoimmune diseases. Recombinant mouse IL-23 was administered to 2-week-old BALB/c female mice. Mice were fed a chow diet and an autoclaved diet throughout the experiments. Intravenous injection of rIL-23 induced glomerulonephritis with proteinuria in mice fed a chow diet. Kidneys were normal in mice fed an autoclaved diet. Serum levels of anti-nucleosome antibody, anti-double-stranded DNA antibody, and anti-nuclear antibody were higher in rIL-23-injected mice fed a chow diet than in mice injected with vehicle alone. Serum levels of anti-U3 RNP antibody were higher in rIL-23-injected mice fed a chow diet than in mice injected with vehicle alone. In contrast, serum levels of anti-nucleosome antibody and anti-U3 RNP antibody were lower in rIL-23-injected mice fed an autoclaved diet than in mice injected with vehicle alone. rIL-23 induced the secretion of IL-17 from T cells. Th17 cell development was suppressed by injection of rIL-23. rIL-23 induced a decrease in IL-10 production by splenic B cells. Treatment with neutralizing anti-IL-23 resulted in increased IL-10 production by splenic B cells, and the development of glomerulonephritis in mice fed a chow diet was suppressed. These results suggest that IL-23 is responsible for the imbalance between Th1- and Th17 82157476af
